About the Project
Eeyouch know that the land, water, and animals are closely tied to their well-being. Nituchischaayihtitaau Aschii is a project to study the links between people's health, the kinds of food they eat, and the contaminants in the environment.

Many of the traditional Eeyou foods are healthy but, these days, some fish and animals may be contaminated with harmful chemicals. Also, some diseases can be passed from animals to the humans.

We need to know whether the benefits of eating traditional food outweigh the risks. To find out, the project asked five questions:
1. Nutrition: What kinds of food are people eating in Eeyou Istchee? What nutrients are people getting from traditional foods?
2. Physical Activity: Are people leading active lives?
3. Contaminants: What contaminants are found in people's bodies?
4. Zoonoses: How many people have caught infections from animals?
5. General Health: Do people have health problems that might be linked to their food choices and to contaminants?

The project is funded by Niskamoon under the 2001 Mercury Agreement between the Crees and Hydro-Québec. It involves all 9 Eeyou communities.

Community Participation
Whapmagoostui was visited in August 2009 and 161 people participated in the study (including babies, children, adults and elders).

Participants gave samples of their hair, nails, urine and blood to be tested for contaminants. They also had their weight and blood pressure measured, and answered questionnaires about their health, eating habits and activities.

Educational Activities
The project’s educational component aimed to make science exciting through fun, hands-on activities. The goal was to encourage young people in Eeyou Istchee to pursue science and health careers.

Workshops about science, recycling and nutrition were held at Badabin Eeyou School and the local child care centre. Forty kids also took part in a Science Summer Camp.

Over 180 kids took part in the educational activities!

Conclusions
People do have some traces of contaminants in their bodies, but this is not a major health concern in Whapmagoostui right now.

However, development projects like the Rupert River hydro project and mining plans will continue to impact the environment. Therefore, it is important to keep checking the levels of contaminants in the environment and in people’s bodies to make sure that they do not reach levels that could impact our health.

Being overweight, eating unhealthy food and lacking physical activity are bigger health problems than contamination. Traditional food remains a healthy choice compared to store-bought foods with high fat and sugar content. The benefits of eating traditional food outweigh the risks!

The priorities for health promotion in Whapmagoostui are:
• Do not smoke
• Be active by walking, doing physical work, and playing sports
• Eat foods high in vitamins like fruits and vegetables
• Cut back on store-bought foods with high fat and sugar
• Keep eating traditional foods as they are healthy

Caribou, goose, and ptarmigan are the most common traditional foods eaten in Whapmagoostui. Over 60% of the people interviewed had eaten these foods in the last year, and this did not depend on age. Fowl and game were eaten more often than fish.

People in Whapmagoostui get enough protein and carbohydrates in their diets. However, most people tend to eat too much fat, saturated fat, and cholesterol. Most people eat enough meat to get plenty of zinc and iron. People in all age groups eat fewer fruits, vegetables, and milk products than recommended. This leads to low levels of important nutrients like calcium, magnesium, and some vitamins.

Children get about 13% of their daily calories from drinking pop and other sweet drinks (not including fruit juice). The extra calories and sugar contribute to being overweight and can lead to diseases like diabetes.

### 2. Physical Activity

In Mistissini, the study found encouraging links between physical activity (especially walking) and better weight. Other studies have established that doing regular physical activity lowers the risk of heart disease, diabetes, and other health problems.

### 3. Contaminants

Contaminants are chemicals like mercury, lead, and pesticides that can be harmful to our health.

Some contaminants are released into the environment by industries in the south and carried north by the wind and rain. Mercury is present naturally in the soil, but developments such as hydroelectric dams and forestry cause mercury to move from the soil into lakes and rivers, where it is absorbed by plants and tiny animals. Contaminants travel up the food chain and accumulate in the fish and animals that we eat.

Our bodies can tolerate a small amount of contaminants, but too much can affect our health. Babies, children and pregnant women are especially vulnerable. The project tested for Mercury, Lead, Cadmium, Arsenic, Selenium, PCBs and other Organic Contaminants, such as pesticides and fire retardants. Mercury levels in blood or hair are lower than they were in the 1970s, but they remain a concern. In Whapmagoostui, one individual required follow-up (but not serious) with a doctor for mercury and 18 for lead (not serious). Lead shot is likely the source of lead. Smoking is the main source of cadmium and also remains a concern (as do PCBs blood levels, which were mid-range compared to the other communities). Although body levels of arsenic were normal, levels in hair of some individuals suggested an external source.

### 4. Zoonoses

Zoonoses are bacteria, germs and viruses that people can catch from animals. Hunters and trappers who come into contact with wild animals may be at risk. When we come into contact with zoonoses, our bodies make antibodies to fight infection. These antibodies stay in our blood for years and can be detected with a blood test.

The study found some traces of past infection by zoonoses, but nobody was currently infected. Often these infections have very few symptoms.

A local group like the CTA could tell hunters and trappers what symptoms to look out for. Health care workers should also be informed about the symptoms of these illnesses.

### 5. General Health (adults 18 years and older)

Some health problems are linked to people’s eating habits and contaminants. These include thyroid problems, heart disease and diabetes.

#### Risk Factors for Heart Disease

- **Weight**
  - 92.1% of participants were overweight.
  - 83.1% can be considered obese.
- **People in Whapmagoostui are more overweight than individuals in Mistissini, Eastmain, Wemindji, Waswanipi, and Chisasibi, with Waskaganish the lowest.**

#### Blood pressure

- 12.5% had high blood pressure.
